

Atomic Structure Summary

- All atoms have:
 - a positively charged **nucleus**
 - and negatively charged **electrons** moving around within atomic orbitals
- Atomic **nucleus** consists of:
 - positively charged **protons**
 - and **neutrons** that have no electric charge
- Atoms are neutral:
of protons = # of electrons

Understanding Elements

The number of protons and neutrons in the nucleus give the atoms their specific characteristics.

- All atoms of the same chemical element contain the same **number of protons**, defined by a unique **atomic number** of that element.
- For example, all helium atoms, and only helium atoms, contain two protons and have an atomic number of 2.
- Atoms are also characterized by:
 - **atomic mass**, "relative isotopic mass" in *unified atomic mass units*, which is roughly (within 1%) equal to the whole mass number (since the mass of a proton and the mass of a neutron are almost the same and the mass of the atom's electrons is negligibly small)
 - **mass number**, which is a **sum of the number of protons and the number of neutrons in the nucleus** (number of *nucleons*)

Periodic Table of Elements

is arranged in order of increasing atomic number

(shown *color-coded* according to discovery timeline from antiquity to 2012)

- Known in antiquity
- also known when (akw) Levoisier published his list of elements (1789)
- akw Mendeleev published his periodic table (1869)
- akw Deming published his periodic table (1923)
- akw Seaborg published his periodic table (1945)
- also known (ak) up to 2000
- ak to 2012

Isotopes are different forms of a given element that have the **same number of *protons*** in each atom but **differ in number of *neutrons***.

Most elements have more than one isotope.

There are 20
Plutonium isotopes,
all of them *unstable!*

- The nucleus of an iron isotope with mass number 56 is more stable than any other element's nucleus (the farther from 56 an element's mass number is, the more unstable that element's nucleus tends to be).
- The heaviest element that still has stable isotopes is **Lead**.

What Holds an Atom Together?

- The electrons are kept in orbit around the nucleus due to an electromagnetic field of attraction between the positive (+) charge of the protons and the negative (-) charge of the electrons.

- The nucleus of protons and neutrons is kept together by the nuclear (strong) force, which *opposes and overcomes the electromagnetic repulsion when particles are very close to each other (~1 fm!)*.

Binding Energy and Atom Stability

Nuclear (binding) energy is the energy associated with the **nuclear force**.

- An unstable atom does not have enough binding energy to hold the nucleus together permanently and will lose neutrons and/or protons as it attempts to become stable...

- A stable atom is an atom that has enough binding energy to hold the nucleus together permanently.

...radioactivity!
